Enhancing Subway's Customer Experience and Operations through Digital Transformation

SUBWAY®

snowflake®

Abstract

This report explores the role of data management in enhancing business performance and customer experience within the context of Subway's ongoing digital transformation. It begins by analysing the company's current data infrastructure, highlighting existing challenges such as fragmented systems, inconsistent reporting, and limited scalability. To address these limitations, the report proposes the implementation of a cloud-based Enterprise Data Warehouse (EDW) using Snowflake, a modern data platform capable of consolidating structured and semi-structured data from various sources including PoS systems, mobile apps, and inventory databases. The proposed solution aims to centralise data access, improve operational responsiveness, and enable real-time decision-making.

An in-depth evaluation of the technology is conducted from both technical and managerial perspectives. The analysis demonstrates how the EDW can enhance data quality, governance, and analytical capabilities while supporting franchise-wide reporting and compliance. Key benefits include improved collaboration, predictive insights, and scalable infrastructure. The report also addresses potential challenges such as cost management, legacy system integration, and user adoption, offering practical mitigation strategies. Overall, the report concludes that implementing a cloud-based EDW positions Subway to operate as a data-first enterprise, enabling it to maintain competitive advantage and deliver consistent, high-quality service across its global operations.

Introduction

Technology is vital in improving customer experience by speeding up communication, offering convenience and supporting users proactively. Chatbots and smartphone applications provide rapid replies and self-service alternatives, minimising the need to wait for help. Analytics software assists firms in identifying and resolving problems before they escalate, whereas customer data systems prevent users from repeating information by keeping it centrally. These advances result in easier, more enjoyable experiences, helping businesses to fulfil increased demands while providing consistent service across all channels (Emil, 2023).

Subway is one corporation that uses technology to improve customer service and operations. Subway, one of the world's leading quick-service restaurant brands, is embarking on a massive digital transformation to enhance guest experience and assist its global network of franchises. Key modifications include enhancements to its app, website and point-of-sale system, all geared at making ordering and servicing speedier (Capgemini, 2025).

Effective data utilisation has become essential as the quick-service restaurant sector becomes more competitive and technologically driven. Subway's continuous transformation demonstrates data's crucial role in improving consumer encounters, optimising internal processes, and allowing rapid decision-making (Consulting.us, 2024). This research examines how Subway may improve performance, scalability, and customer happiness through data-driven initiatives by critically examining its current data management infrastructure and investigating the incorporation of innovative technologies.

Subway partnered with Capgemini to lead the change and provide innovative, scalable technological solutions. They worked together to build digital platforms, automate menu changes and increase system integration to ensure seamless operations. These initiatives have resulted in higher customer happiness, faster service and more digital sales (Capgemini, 2025) This report will examine the subway's current data management strategy, propose a new technology to meet its objective, and assess how this change might lead to further technical and business advantages.

Company Identification & Existing Data Management Strategy

Subway is one of the world's largest quick-service restaurant (QSR) chains, with approximately 37,000 locations in over 100 countries. It provides millions of consumers with freshly prepared sandwiches, wraps, salads and bowls daily. Subway is embarking on a long-term digital transformation to stay competitive in a rapidly changing industry and fulfil growing customers expectations, streamline internal processes and provide more efficient assistance to franchise owners (Capgemini, 2025).

Subway's transformation is driven by four fundamental strategies: improved food, operational excellence, more access and convenience via digital technologies, and dynamic business development. Subway collaborated with Capgemini, a multinational technology and consulting organisation to assist these objectives. Capgemini helps Subway with both strategic and technical implementation. Their partnership focuses on modernising the subway's digital

infrastructure, enhancing processes, and offering professional assistance to help build the company's digital strategy (Capgemini, 2025).

Initially, Subway's digital platform was developed for North America and was not well adapted to foreign development. In 2019, the company began updating its digital infrastructure to serve its global customers better. However, when the COVID-19 pandemic started, the subway had to rethink its objectives. The company rapidly updated its app and website to enable digital ordering and curbside pickup. The previous systems were no longer suitable for these requirements. Thus, they were replaced with modern, user-friendly platforms that function well on web and mobile devices (Capgemini, 2025).

Along with these developments, the subway improved its technological backbone. This involved modernising its API system and infrastructure to enhance integration and scalability. These enhancements facilitated the global spread of digital services and allowed the organisation to manage higher quantities of online orders. One of the most significant improvements was the direct connection of digital orders with the in-store point-of-sales (PoS) system, which allows restaurant employees to manage digital orders as easily as walk-in orders. As a result of these adjustments, Subway's global sales increased. As a result of these adjustments, subway's global digital sales increased significantly by double digits from 2021 to 2022 and tripled since 2019 (Capgemini, 2025).

Beyond the ordering system, Subway enhanced catering and inventory management. The company streamlined online catering by offering speedier ordering and new menu selections. It also launched smart fridges, which allow customers to purchase fresh food without stepping inside a shop and are refreshed daily by local franchises. Subway overhauled its point-of-sale and menu platforms, which were both effective and outdated. Managing menu revisions was a significant challenge, as each location had to make over 30 modifications each year, totalling over a million changes globally. Many franchises avoid upgrades because they are time-consuming, affecting promotions and customer satisfaction (Capgemini, 2025).

To address this, Subway and Capgemini developed an automated menu publication system. Now, changes are managed centrally and distributed across all platforms, saving franchises time and effort. Franchises retain control over pricing and what they provide, but the technical load is significantly reduced. Another significant enhancement was in stock management. If an item is out of stock, staff can make it inaccessible on all platforms simultaneously, preventing customers from buying unavailable products. This method is far faster than the prior manual procedure. The PoS interface was also modified to be more user-friendly, particularly for younger staff accustomed to touchscreens. These adjustments have increased service speed and decreased employee mistakes (Capgemini, 2025).

In conclusion, Subway has dramatically improved its digital infrastructure and data management processes, improving both the client experience and franchise operations. While obstacles continue, particularly with outdated backend infrastructure, Subway's cooperation with Capgemini assists the company in transitioning to a more flexible and modern digital environment. This transformation is about more than just technology; it promotes long-term business success and provides superior service across all channels (Capgemini, 2025).

Proposal of an Additional Data Management Technology

Subway should install a cloud-based enterprise data warehouse (EDW) like Snowflake to provide a unified view of customer data, enhance campaign performance, reduce churn, and drive revenue growth. They also support predictive analytics, enabling data-driven forecasting and strategic decision-making (Snowflake, 2023). Subway has made progress in updating its point-of-sale systems, automating menu changes, and integrating curbside pickup. Still, it continues to rely on antiquated infrastructure, which hinders global analytics, governance, and seamless data access across geographies (Capgemini, 2025). A centralised EDW would alleviate these concerns while improving Subway's capacity to make large-scale data-driven choices.

Snowflake offers a powerful, cloud-native EDW that separates storage from processing, allowing Subway to grow performance regardless of capacity requirements. Unlike traditional data warehouses, Snowflake handles semi-structured data, such as JSON, which is increasingly important in omnichannel applications. This feature is critical to Subway's operations, which now include web, smartphone, in-store, and smart fridge orders, all of which create unique datasets (Snowflake, 2023). The solution enables real-time ingestion via ETL/ELT pipelines and integrates seamlessly with Subway's current cloud infrastructure, which includes PoS systems, APIS, CRM tools, and guest feedback platforms (Gupta, 2023). Subway can gain a holistic picture of customer habits, supply chain dynamics, and franchisee performance by combining all of these data sources in a single platform (Snowflake, 2023).

Snowflake's flexibility enables Subway to integrate data from its current digital channels, such as its mobile app, online catering platform, and in-store technology, into a single accessible environment. Tools like Fivetran could automate data pipelines between operational systems and the warehouse (Fivetran, 2023), (Gupta, 2023). Subway's analytics and strategy teams might then utilise BI solutions like Tableau or Power BI to create real-time dashboards for decision-makers. Franchisees may also receive personalised performance statistics, inventory trends, and consumer preferences via role-based dashboards particular to their locations.

Adopting a cloud-based EDW will help Subway improve its data governance and compliance system. Currently, maintaining changes across thousands of franchisees is time-consuming and inconsistent. Snowflake's role-based access management and sharing capabilities allow Subway to securely share standardised data models and reporting tools to stakeholders while

maintaining data privacy across jurisdictions. This is especially significant for a corporation operating in over 100 countries with diverse regulatory frameworks. The technology would also let Subway track and adapt to new trends, such as increased demand for contactless services or regional menu preferences (NerdySeal, 2022).

Furthermore, a contemporary EDW enables enhanced analytics and AI integration. Subway may use machine learning algorithms to estimate ingredient demand, improve staffing schedules, and tailor marketing offers based on customer behaviour. With these skills, Subway might shift from reactive to predictive operations. This would change Subway to a data-first operating strategy, offering it a strategic advantage in the competitive quick-service restaurant business (Assur & Rowshankish, 2022).

Implementing a cloud-based business data warehouse like Snowflake would considerably improve Subway's data management capabilities. It would enable real-time decision-making, predictive analytics, streamlined governance, and increased operational efficiency throughout its worldwide franchise network. This technology is ideal for Subway's expanding digital architecture and would help the company achieve its long-term objective of becoming a data-driven, agile corporation.

Evaluation of the Proposed Technology

Subway's EDW is at the core of its data ecosystem. The warehouse receives data from various sources, including point-of-sale terminals, mobile apps, and inventory systems (SnowFlake, 2025). The EDW components are located in the centre and handle transformation, storage, and analytics functions (FasterCaptial, 2025). On the right, business users from various departments (corporate leadership, marketing, supply chain, and franchise operations) consume insights through dashboards and analytical tools. This arrangement enables real-time visibility and informed decision-making at all company levels.

The EDW offers executive dashboards that track key KPIS such as franchisee performance, digital engagement trends, and profitability measures. Senior executives can monitor worldwide performance and respond proactively to company changes. Franchise managers utilise the same infrastructure to track store-level metrics such as sales performance, labour utilisation, and customer feedback (Quikserve, 2022). This enables them to make quick, local choices consistent with company objectives. The marketing team benefits from having unified access to consumer behaviour data, which allows them to run hyper-personalised campaigns and track promotional efficacy. In supply chain management, insights generated from the EDW assist in predicting demand surges, managing procurement, and decreasing inventory waste (FoodLogistics, 2007).

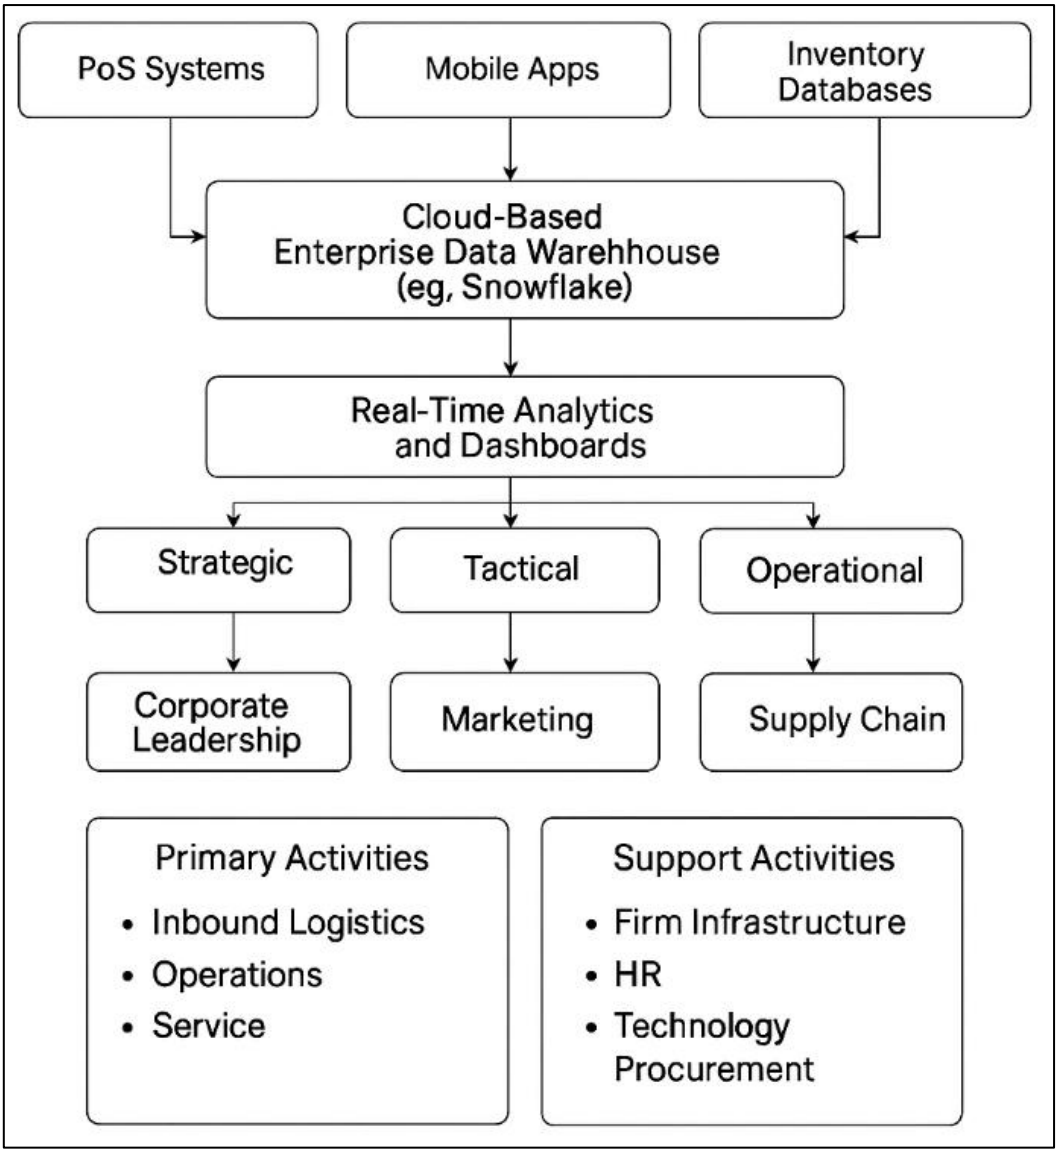

Figure 1 Cloud-Based EDW Flow Architecture

Figure 1 shows the strategic level, senior leadership accesses KPIS via the EDW, including supply chain efficiency, franchise profitability, and customer loyalty trends. This influences company planning, growth plans, and long-term resource allocation (Jackson, 2025). At the tactical level, marketing managers examine behavioural data to improve campaigns, while supply chain teams use real-time alerts to predict demand peaks or problems (O'Malley, 2025). At the operational level, store managers use performance dashboards to enhance day-to-day operations such as staff scheduling, stock modifications, and customer service resolution (Quikserve, 2022). This alignment across decision levels demonstrates how Subway transforms raw data into valuable insight, enabling nimble management from headquarters to the restaurant floor (Romero, 2024).

This digital infrastructure is further contextualised in the comprehensive EDW Integration Diagram, which offers a layered visual overview of Subway's enterprise-wide data transformation strategy (Silva, 2024).

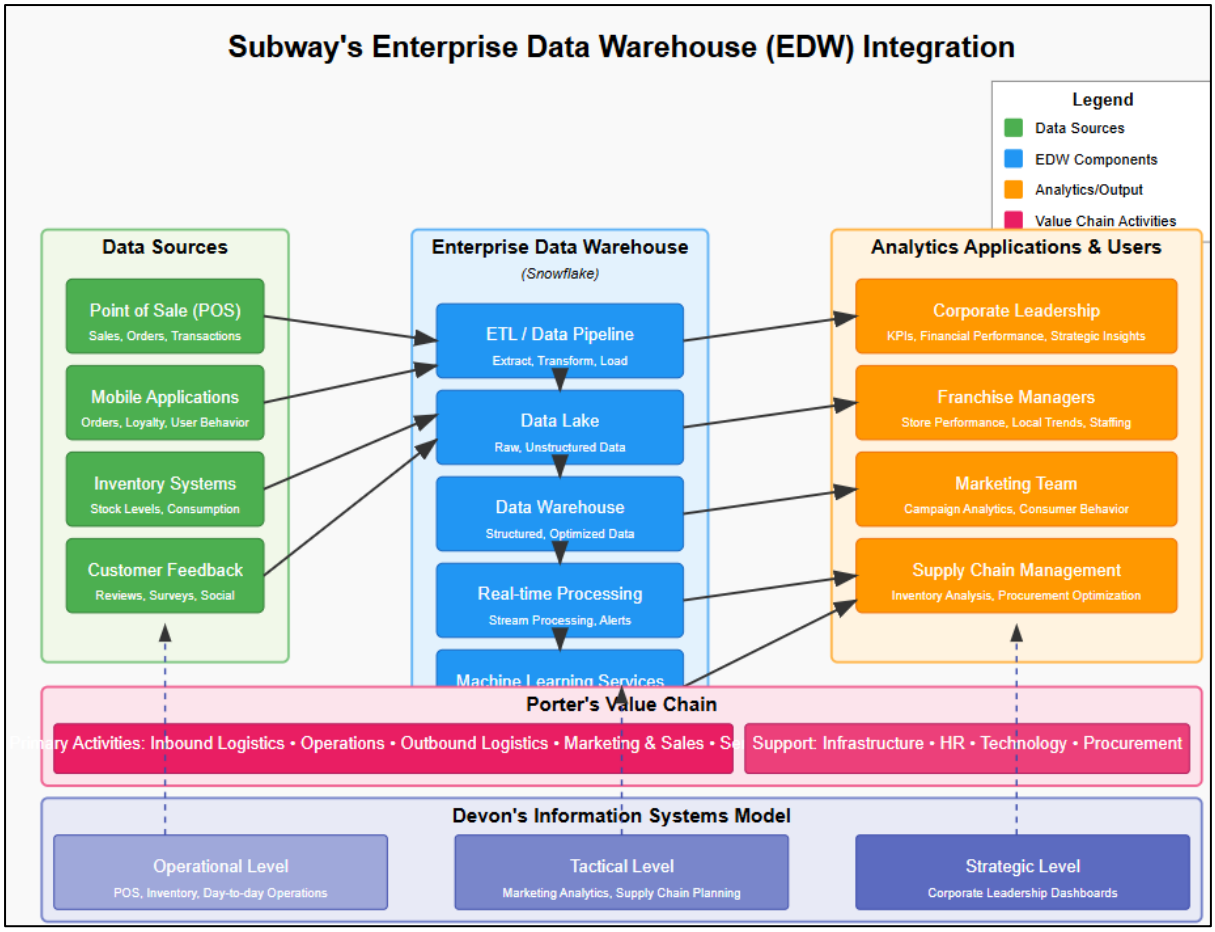

Figure 2 Subway's Enterprise Data Warehouse (EDW) Integration Overview (AltexSoft, 2022)

Figure 2 Demonstrate the relationship between EDW components and Subway business units. Data from operational systems enters a processing pipeline, where it is grouped into data lakes and structured warehouses (Sargo, 2020). End users from many departments, including corporate leadership, franchise managers, marketing, and supply chain teams, ask these questions. The integration allows for performance monitoring and advanced features like predictive analytics, machine learning, and customer segmentation (Shipley, 2025).

Subway's model implementation successfully aligns with Porter's Value Chain, distinguishing between major activities (inbound logistics, operations, sales, and service) and support activities (infrastructure, human resources, procurement, and technology). On the primary side, consolidated analytics improves inventory forecasting, real-time order tracking, and customer support automation (Auer, 2024). Meanwhile, support areas like personnel management benefit from integrated HR data, while procurement obtains visibility through vendor performance and buy processes.

The system also adheres to Devon's Information Systems Model concepts, prioritising data flow across three tiers: operational, tactical, and strategic. Using a real-time analytics layer between raw data inputs and business users, Subway enables its employees to obtain insights for their jobs and choices at the proper degree of granularity (Richman, 2024). The methodology guarantees that frontline personnel receive the data required for quick action, while executives access long-term trends and cross-regional comparisons (Imran, 2023).

Furthermore, Subway has collaborated with MindStream Analytics to implement the NetSuite Analytics Warehouse, focusing on data integration, security, and user training. This initiative has streamlined data management processes and enhanced reporting capabilities, particularly within the Finance and IT departments (MindStreamAnalytics, 2025).

In terms of automation, Subway adopted ActiveBatch's workload automation tools to manage complex workflows efficiently. This transition reduced the time spent on building and updating workflows by approximately 75%, allowing for dynamic management of workflows and dependencies from a central console (ActiveBatch, 2025).

Equally significant is the EDW's role in data governance. Subway uses built-in role-based access controls (RBAC) to manage user rights by department, region, or seniority. This assures compliance with GDPR and CCPA, especially when dealing with personal or transactional data. Snowflake also offers auditing capabilities, metadata tagging, and encryption, which improve Subway's capacity to enforce standards across its franchise network (Raman, 2024).

Despite these benefits, EDW deployment does not come without hazards. One significant difficulty is data migration. Transferring historical datasets to a new architecture requires time, accuracy, and testing. Misconfigured ETL processes or incorrect data schemas can result in mistakes that spread across analytics and reporting. A staged migration plan must be minimised, including sandbox environments and rollback procedures (AltexSoft, 2022).

Another major impediment is the unpredictability of costs. Cloud solutions like Snowflake have a use-based pricing approach, meaning prices might rise if consumption is not managed. Subway must adopt automatic budget controls and provide dashboards that track and compute expenses in real time. Pre-negotiated corporate license or limited payment tiers might be utilized to decrease financial risk further (SnowFlake Docs, 2025).

Subway must also consider organisational adoption. Franchisees may resist the change from old reporting systems to interactive dashboards. To solve this, Subway could establish a training program and provide continuing user assistance to help overcome digital skills gaps. A centralised Cloud Centre of Excellence (CCoE) may lead to best practices, information sharing, and troubleshooting to improve user acceptance and promote innovation.

Finally, consider the issue of vendor lock-in. Relying solely on one source raises strategic vulnerability. To mitigate this risk, Subway might implement a hybrid-cloud approach that includes data replication and fallback alternatives on alternate platforms. Open-source ETL tools and portable data formats further minimise reliance on proprietary systems (Kropov, 2023).

Despite these challenges, the long-term strategic benefits of implementing EDW considerably exceed the dangers. By leveraging accurate, real-time data, Subway may bring innovations like AI-driven demand forecasts, dynamic pricing, and sustainability indicators. It also improves franchisee empowerment, the customer experience, and operational agility. Most crucially, the EDW allows Subway to transition from a reactive, separate data environment to a predictive, intelligent enterprise (Romero, 2024).

Evaluation of the Recommended Technology

Implementing a cloud-based Enterprise Data Warehouse (EDW), such as Snowflake, provides more than increased data access; it also represents a strategic shift in how Subway operates across its franchise network. One of the platform's most significant advantages is its ability to handle multi-tenant setups, which allows Subway to provide franchisees with access to performance dashboards while preserving central data control. This mix of autonomy and control is critical for a global franchise model and provides significant managerial benefits. Decision-makers at all levels, from corporate strategy teams to local shop managers, may have customised information, resulting in more agile reactions and consistent execution (SnowFlake, 2021).

From a technological point of view, Snowflake's separation of computing and storage enables Subway to expand resources dynamically in response to seasonal demand or data volume. This flexibility eliminates system bottlenecks and allows many workloads, such as real-time customer analytics and batch reporting, to operate concurrently without compromising performance (SnowFlake Docs, n.d.). Importantly, the platform's support for semi-structured data means that insights from mobile app usage, customer evaluations, and operational input can be combined in a single environment, increasing analytical richness. Built-in capabilities like automatic backups, version control, and cross-departmental data exchange improve technical reliability (Gupta, 2025).

However, adopting Snowflake raises new issues that must be addressed carefully. Technical teams must solve integration challenges with legacy systems, while leadership must provide sufficient training and communication to franchisees during the transition period (Sobotík, 2022). Another factor to consider is cost management; usage-based pricing structures can become unpredictable without proper controls. Mitigation measures include staggered deployment plans, resource tracking, and workload monitoring to prevent overspending (Anand, et al., 2024). These risks may be mitigated by proactive governance and cross-functional collaboration, allowing Subway to maximise the value of its investment.

Conclusion

Subway's digital transformation demonstrates the rising importance of strong data management in achieving operational efficiency, customer happiness, and strategic agility. The review of its present systems demonstrates tremendous progress in digitising its services and infrastructure, notably thanks to its collaboration with Capgemini. However, limits in legacy data architecture, scalability, and advanced analytics capabilities call for a more integrated and adaptable solution. The suggested usage of a cloud-based Enterprise Data Warehouse (EDW), such as Snowflake, directly solves these shortcomings by centralising data access, allowing for real-time analytics, and providing safe, scalable, and efficient data handling throughout the worldwide franchise network.

The examination of this technology indicates its ability to improve technical performance and managerial decision-making at Subway. It enables better collaboration, predictive capabilities, and faster execution while meeting global data compliance and governance requirements.

While difficulties like cost management, legacy integration, and user adoption need careful planning, they are solvable with phased deployment and good governance. Finally, implementing an EDW enables Subway to become a data-first corporation capable of maintaining a competitive edge while providing consistent, high-quality experiences to consumers and franchisees alike.
